

## Lecture Outline

1. Bottom-up parsing
2. LR(1) parsing
3. Constructing a simple LR(1) parser
4. DFA for viable prefixes

## 1. Bottom-up Parsing

- Bottom-up parsing can be viewed as trying to find a rightmost derivation in reverse for an input string.
- A *handle* is a rightmost substring in right-sentential form that matches the body of a production and whose reduction by that production represents one step in the reverse of the rightmost derivation.
  - Consider the grammar  $G$ :

(1)  $S \rightarrow S ( S )$   
 (2)  $S \rightarrow \epsilon$

- The handles in a rightmost derivation for the input string  $( ) ( )$ :

$S \rightarrow S ( S )$  // handle is  $S ( S )$   
 $\rightarrow S ( )$  // handle is the empty string between  $( )$   
 $\rightarrow S ( S ) ( )$  // handle is  $S ( S )$   
 $\rightarrow S ( ) ( )$  // handle is the empty string between first  $( )$   
 $\rightarrow ( ) ( )$  // handle is the empty string prefix

- Shift-reduce parsing* is a form of bottom-up parsing in which we shift terminal symbols of the string to be parsed onto a stack until a handle appears on top of the stack. We then replace the handle by the nonterminal symbol on the left-hand side of the associated production (this is a "reduce" action). We keep repeating this process until we have reduced the input string to the start symbol of the grammar. This process simulates the reverse of a rightmost derivation for the input string. Thus, we can think of shift-reduce parsing as "handle pruning."

## 2. LR(1) Parsing

- Model of an LR(1) parser (Fig. 4.35).
- "L" means left-to-right scanning of the input, the "R" means constructing a rightmost derivation in reverse, and the "1" means one symbol of lookahead in making parsing decisions.
- LR parsing table for  $G$ :

State	Action			Goto
	(	)	\$	
0	r2	r2	r2	1
1	s2		acc	
2	r2	r2	r2	3
3	s2	s4		
4	r1	r1	r1	

r2 means reduce the handle on top of the stack by production (2)  $S \rightarrow \epsilon$ .

s2 means shift the input symbol on the stack and then push state 2 on top of the stack.

acc means accept and stop parsing.

Goto[0,S] = 1 means push state 1 on top of the stack after reducing a handle to the nonterminal  $S$  in state 0.

A blank entry means report a syntax error.

- Moves made by an LR(1) parser on input  $( ) ( )$  [Alg. 4.44].

Stack	Input	Action
0	$( ) ( ) \$$	reduce by (2) $S \rightarrow \epsilon$ ; push state 1 on stack

0S1	()()	\$	shift ( on stack; push state 2 on stack
0S1(2	()()	\$	reduce by (2) $S \hat{\rightarrow} \hat{\mu}$ and push state 3
0S1(2S3	()()	\$	shift ( and push state 2
0S1(2S3)4	()	\$	reduce by (1) $S \hat{\rightarrow} S(S)$ and push state 1
0S1	()	\$	shift ( and push state 2
0S1(2	()	\$	reduce by (2) $S \hat{\rightarrow} \hat{\mu}$ and push state 3
0S1(2S3	()	\$	shift ) and push state 4
0S1(2S3)4		\$	reduce by (1) $S \hat{\rightarrow} S(S)$ and push state 1
0S1		\$	accept

- Note that an LR parser is a shift-reduce parser that traces out a rightmost derivation in reverse.

### 3. Constructing a Simple LR(1) Parsing Table for a Grammar

- An  $LR(0)$  item of a grammar is a production of the grammar with a dot at some position of the right side. E.g.,  $S \hat{\rightarrow} \hat{A} \cdot S(S)$ ,  $S \hat{\rightarrow} S \hat{A} \cdot (S)$ , or  $S \hat{\rightarrow} S(S) \hat{A} \cdot$ .
- We will use two functions to construct the sets of items for a grammar:
  - $closure(I)$ , where  $I$  is a set of items, is the set of items constructed by the following two rules:
    1. Initially, put every item in  $I$  into  $closure(I)$ .
    2. If  $A \hat{\rightarrow} \hat{I} \pm \hat{A} \cdot \hat{B} \hat{I}^2$  is in  $closure(I)$  and  $B \hat{\rightarrow} \hat{A} \cdot \hat{I}^3$  is a production, then add the item  $B \hat{\rightarrow} \hat{A} \cdot \hat{I}^3$  to  $closure(I)$  if it is not already there. Keep repeating this step until no more new items can be added to  $I$ .
  - $goto(I, X)$ , where  $I$  is a set of items and  $X$  is a grammar symbol, is the closure of the set of all items  $A \hat{\rightarrow} \hat{I} \pm X \hat{A} \cdot \hat{I}^2$  where  $A \hat{\rightarrow} \hat{I} \pm \hat{A} \cdot X \hat{I}^2$  is in  $I$ .
- An *augmented* grammar  $G'$  is one to which we have added a new starting production  $S' \hat{\rightarrow} S$  where  $S$  is the start symbol of the given grammar  $G$ . Reducing by the new starting production signals acceptance of the input string being parsed. We will always augment a grammar when we construct an SLR parsing table for it.
- The sets-of-items construction
  - Input: An augmented grammar  $G'$ .
  - Output:  $C$ , the canonical collection of sets of  $LR(0)$  items for  $G'$ .
  - Method:

```

I0 = closure({[S'  $\hat{\rightarrow}$   $\hat{A} \cdot S$ ]});
C = {I0};
repeat
  for each set of items I in C and grammar symbol X such that
    goto(I,X) is not empty and not in C do
      add goto(I,X) to C;
until no more sets of items can be added to C;
```

- Example: Given the augmented grammar  $G'$

```

S'  $\hat{\rightarrow}$  S
S  $\hat{\rightarrow}$  S(S)
S  $\hat{\rightarrow}$   $\hat{\mu}$ 
```

$C$ , the canonical collection of sets of  $LR(0)$  items for  $G'$ , is

```

I0: S'  $\hat{\rightarrow}$   $\hat{A} \cdot S$ 
      S  $\hat{\rightarrow}$   $\hat{A} \cdot S(S)$ 
      S  $\hat{\rightarrow}$   $\hat{A} \cdot$ 
```

```

I1: S'  $\hat{\rightarrow}$  S  $\hat{A} \cdot$ 
      S  $\hat{\rightarrow}$  S  $\hat{A} \cdot (S)$ 
```

```

I2: S  $\hat{\rightarrow}$  S( $\hat{A} \cdot S$ )
      S  $\hat{\rightarrow}$   $\hat{A} \cdot S(S)$ 
      S  $\hat{\rightarrow}$   $\hat{A} \cdot$ 
```

```

I3: S  $\hat{\rightarrow}$  S(S  $\hat{A} \cdot$ )
      S  $\hat{\rightarrow}$  S  $\hat{A} \cdot (S)$ 
```

```

I4: S'  $\hat{\rightarrow}$  S(S)  $\hat{A} \cdot$ 
```

- Algorithm to construct the SLR(1) parsing table from  $C$ , the canonical collection of sets of LR(0) items for an augmented grammar  $G'$
- Input:  $C = \{I_0, I_1, \dots, I_n\}$ .
- Output: The SLR parsing table functions `action` and `goto`.
- Method:
  - State  $i$  and its `action` and `goto` functions are constructed from  $I_i$  as follows:
    - If item  $[A\hat{a}\dagger' \hat{I}\pm\hat{A}\cdot a\hat{I}^2]$  is in  $I_i$  and  $\text{goto}(I_i, a) = I_j$ , then add "shift  $j$ " to `action`[ $i, a$ ]. Here  $a$  is a terminal.
    - If item  $[A\hat{a}\dagger' \hat{I}\pm\hat{A}\cdot]$  is in  $I_i$ , then add "reduce  $A\hat{a}\dagger' \hat{I}\pm$ " to `action`[ $i, a$ ] for all  $a$  in  $\text{FOLLOW}(A)$ . Here  $A$  cannot be  $S'$ .
    - If item  $[S'\hat{a}\dagger' S\hat{A}\cdot]$  is in  $I_i$ , then add "accept" to `action`[ $i, \$$ ].
  - If  $\text{goto}(I_i, A) = I_j$ , then in the parsing table set `goto`[ $i, A$ ] =  $j$ .
  - The initial state of the parser is constructed from the set of items containing  $[S'\hat{a}\dagger' \hat{A}\cdot S]$ .
- Notes:
  - If each parsing table entry has at most one action, then the grammar is said to be *SLR(1)*. If any entry has more than one action, then the algorithm fails to produce a parser.
  - All undefined entries are made `error`.
- Example: the LR parsing table above is an SLR(1) parsing table for the balanced-parentheses grammar.

#### 4. DFA for Viable Prefixes

- A *viable prefix* is a prefix of a right sentential form that does not continue past the right end of the rightmost handle of that sentential form.
- The shift and goto functions of the canonical collection of sets of LR(0) items for a grammar  $G$  define a DFA that recognizes the viable prefixes of  $G$ .
- An item  $[A\hat{a}\dagger' \hat{I}^2\hat{A}\cdot\hat{I}^3]$  is *valid* for a viable prefix  $\hat{I}\pm\hat{I}^2$  if there is a rightmost derivation from  $S'$  to  $\hat{I}\pm\hat{A}w$  to  $\hat{I}\pm\hat{I}^2\hat{I}^3w$ .

#### 5. Practice Problems

Consider the following grammar  $G$ :

- (1)  $S\hat{a}\dagger' S S +$
- (2)  $S\hat{a}\dagger' S S *$
- (3)  $S\hat{a}\dagger' a$

- Construct a rightmost derivation and parse tree for the input string  $aaa^*+\$$ .
- Show the handle in each sentential form in the derivation.
- Construct the canonical collection of sets of LR(0) items for the augmented grammar.
- Construct an SLR(1) parsing table for  $G$ .
- Show how your SLR(1) parser processes the input string  $aaa^*+\$$ .
