3. FOLLOW
4. How to construct a predictive parsing table
5. LL(1) grammars
6. Transformations on grammars

## 1. Review

- Top-down parsing consists of constructing or tracing a parse tree for an input string starting from the root and creating the nodes of the parse tree in preorder.
- Recursive-descent parsing is a top-down method of syntax analysis in which a set of recursive procedures is used to process the input string with a procedure associated with each nonterminal of the grammar. See Fig. 4.13, p. 219.
- A nonrecursive predictive parser uses an explicit stack and a parsing table to do deterministic top-down parsing.
- In this class we will develop an algorithm to construct a predictive parsing table for a large class of useful grammars called LL(1) grammars.
- For this algorithm we need two functions on grammars, FIRST and FOLLOW.

## 2. FIRST

- $\text{FIRST}(\hat{I})$  is the set of terminal symbols that begin the strings derivable from a string of terminal and nonterminal symbols  $\hat{I}$  in a grammar. If  $\hat{I}$  can derive  $\hat{\mu}$ , then  $\hat{\mu}$  is also in  $\text{FIRST}(\hat{I})$ .
- Algorithm to compute  $\text{FIRST}(X)$ :
  1. If  $X$  is a terminal, then  $\text{FIRST}(X) = \{ X \}$ .
  2. If  $X \hat{\rightarrow} \hat{\mu}$  is a production, then add  $\hat{\mu}$  to  $\text{FIRST}(X)$ .
  3. If  $X \hat{\rightarrow} Y_1 Y_2 \dots Y_k$  is a production for  $k \neq 1$ , and for some  $i \leq k$ ,  $Y_i Y_{i+1} \dots Y_{i-1}$  derives the empty string, and  $a$  is in  $\text{FIRST}(Y_i)$ , then add  $a$  to  $\text{FIRST}(X)$ . If  $Y_1 Y_2 \dots Y_k$  derives the empty string, then add  $\hat{\mu}$  to  $\text{FIRST}(X)$ .
- **Example.** Consider the grammar  $G$ :

$$S \hat{\rightarrow} ( S ) S \mid \hat{\mu}$$

For  $G$ ,  $\text{FIRST}(S) = \{ (, \hat{\mu} \}$ .

## 3. FOLLOW

- $\text{FOLLOW}(A)$  is the set of terminals that can appear immediately to the right of  $A$  in some sentential form in a grammar. Let us assume the string to be parsed is terminated by an end-of-string endmarker  $\$$ . Then if  $A$  can be the rightmost symbol in some sentential form, the right endmarker  $\$$  is also in  $\text{FOLLOW}(A)$ .
- Algorithm to compute  $\text{FOLLOW}(A)$  for all nonterminals  $A$  of a grammar:
  1. Place  $\$$  in  $\text{FOLLOW}(S)$  where  $S$  is the start symbol of the grammar.
  2. If  $A \hat{\rightarrow} \hat{I} \hat{B}$  is a production, then add every terminal symbol  $a$  in  $\text{FIRST}(\hat{I})$  to  $\text{FOLLOW}(B)$ .
  3. If there is a production  $A \hat{\rightarrow} \hat{I} B$ , or a production  $A \hat{\rightarrow} \hat{I} \hat{B}$ , where  $\text{FIRST}(\hat{I})$  contains  $\hat{\mu}$ , then add every symbol in  $\text{FOLLOW}(A)$  to  $\text{FOLLOW}(B)$ .
- **Example.** For  $G$  above,  $\text{FOLLOW}(S) = \{ , \$ \}$ .

## 4. How to Construct a Predictive Parsing Table

- Input: Grammar  $G$ .
- Output: Predictive parsing table  $M$ .
- Method:

```

for (each production  $A \hat{\rightarrow} \hat{I}$  in  $G$ ) {
  for (each terminal  $a$  in  $\text{FIRST}(\hat{I})$ )
    add  $A \hat{\rightarrow} \hat{I}$  to  $M[A, a]$ ;
  if ( $\hat{\mu}$  is in  $\text{FIRST}(\hat{I})$ )
    for (each symbol  $b$  in  $\text{FOLLOW}(A)$ )

```

```

        add  $A \rightarrow \hat{I} \pm$  to  $M[A, b]$ ;
    }
    make each undefined entry of  $M$  be error;

```

• **Example 1.** Predictive parsing table for the grammar:

$S \rightarrow +SS \mid *SS \mid a$ ;

$FIRST(S) = \{+, *, a\}$

$FOLLOW(S) = \{+, *, a, \$\}$

Nonterminal	Input Symbol			
	a	+	*	\$
S	$S \rightarrow a$	$S \rightarrow +SS$	$S \rightarrow *SS$	<b>error</b>

• **Example 2.** Predictive parsing table for the grammar:

$S \rightarrow (S)S \mid \epsilon$

$FIRST(S) = \{ (, \epsilon \}$

$FOLLOW(S) = \{ ), \$ \}$

Nonterminal	Input Symbol		
	(	)	\$
S	$S \rightarrow (S)S$	$S \rightarrow \epsilon$	$S \rightarrow \epsilon$

• **Example 3.** Predictive parsing table for the grammar:

$S \rightarrow S(S) \mid \epsilon$

$FIRST(S) = \{ (, \epsilon \}$

$FOLLOW(S) = \{ (, ), \$ \}$

Nonterminal	Input Symbol		
	(	)	\$
S	$S \rightarrow S(S)$ $S \rightarrow \epsilon$	$S \rightarrow \epsilon$	$S \rightarrow \epsilon$

## 5. LL(1) Grammars

- A grammar is LL(1) iff whenever  $A \rightarrow \hat{I} \pm \mid \hat{I}^2$  are two distinct productions, the following three conditions hold:
  - For no terminal  $a$  do both  $\hat{I} \pm$  and  $\hat{I}^2$  derive strings beginning with  $a$ .
  - At most one of  $\hat{I} \pm$  and  $\hat{I}^2$  can derive the empty string.
  - If  $\hat{I}^2$  derives the empty string, then  $\hat{I} \pm$  does not derive any string beginning with a terminal in  $FOLLOW(A)$ .  
Likewise, if  $\hat{I} \pm$  derives the empty string, then  $\hat{I}^2$  does not derive any string beginning with a terminal in  $FOLLOW(A)$ .
- We can use the algorithm above to construct a predictive parsing table with uniquely defined entries for any LL(1) grammar.
- The first "L" in LL(1) means scanning the input from left to right, the second "L" for producing a leftmost derivation, and the "1" for using one symbol of lookahead to make each parsing action decision.

## 6. Transformations on Grammars

- Two common language-preserving transformations are often applied to grammars to try to make them parsable by top-down methods. These are eliminating left recursion and left factoring.
- Eliminating left recursion:
  - Replace

```

expr  $\rightarrow$  expr + term
     $\mid$  term

```

by

```
expr → term expr'
expr' → + term expr'
      | ε
```

- Left factoring:
- Replace

```
stmt → if ( expr ) stmt else stmt
      | if (expr) stmt
      | other
```

by

```
stmt → if ( expr ) stmt stmt'
      | other
stmt' → else stmt
      | ε
```

## 7. Practice Problems

Consider the following grammar G for Boolean expressions:

```
B → B or T | T
T → T and F | F
F → not B | ( B ) | true | false
```

- What precedence and associativity does this grammar give to the operators and, or, not?
- Compute FIRST and FOLLOW for each nonterminal in G.
- Transform G into an equivalent LL(1) grammar G'.
- Construct a predictive parsing table for G'.
- Show how your predictive parser processes the input string

```
true and not false or true
```

Draw the parse tree traced out by your parser.
